Thirty Days on Hyperliquid: A Walk-Forward Evaluation of TradingAgents on the Bitcoin Perpetual, October 2026

Romain Veurrier*

31 October 2026

Abstract

We ran TradingAgents, a multi-agent LLM trading desk, walk-forward on the Bitcoin perpetual future on Hyperliquid for every day of October 2026. Each of its 30 daily decisions saw only information available before its cutoff. Each was executed after the cutoff and paid taker fees, slippage and hourly funding. The Portfolio Manager could choose leverage of up to 5×.

The desk returned -0.53% net while Bitcoin fell -7.37% and a buy-and-hold long returned -8.13%. Its maximum drawdown was 3.71% against 12.60%. It never used leverage and never took a full-size position.

The outperformance is not evidence of forecasting skill:

- It called the next day's direction correctly on 14 of 30 days (Pesaran–Timmermann $p = 0.731$).
- The rank correlation between its ratings and the next day's return was -0.13.
- Only 29% of random reorderings of its own decisions did worse than the desk.

An exposure-versus-timing decomposition locates the result. The desk's average net-short stance (-0.23× equity) earned +1.65%, its day-to-day timing contributed -1.98%, and costs -0.24%. Two simple trend rules, 30-day momentum and MACD, earned +9.16% and +8.12% in the same month.

Replaying the same decisions at fixed leverage shows what the 40× the venue offers would have done: the account is liquidated on 21 October. We also report:

- stationary-bootstrap intervals, which are wide (Sharpe ratio between -5.43 and 4.41);
- the deflated Sharpe ratio;
- cost and policy sensitivities;
- a leakage audit of the data and of the models' pretraining;
- a measure of how often the desk changes its mind when re-run on identical inputs.

One month cannot establish skill. It can show that a carefully priced, leakage-free LLM desk behaves conservatively, survives, and does not time the market.

1 Introduction

LLM trading agents are usually evaluated in backtests that are hard to trust. The data the agents read is not always point-in-time. Execution is often assumed at the price that produced the signal. Financing costs are ignored. And the models may simply remember the test period [1, 3].

The companion paper adapts TradingAgents [5] to Bitcoin perpetual futures on Hyperliquid and specifies an evaluation protocol that closes these channels. This paper runs the protocol for one month, October 2026, and asks three questions:

*Prepared with the assistance of Claude (Anthropic), which ran the experiment and drafted this text under the author's direction. Code, data cache, ledger and agent reports: branch `hyperliquid-btc` of `https://github.com/romainveurrier/TradingAgents`, directory `experiments/hl_btc_2026-10`.

1. **What does the desk do?** Its ratings, positions and use of leverage, and how its analysts, researchers, trader and portfolio manager interact.

2. **How did it perform, net of everything a venue charges,** against buy-and-hold and simple rules?

3. **Is there evidence of skill?** Directional accuracy, timing tests, random-decision benchmarks and intervals. We also ask how much of any result is the month rather than the agents.

Findings.

- *Behavior.* The desk is cautious and consistent. It issued only half-size ratings (22 Underweight, 7 Overweight, 1 Hold) and chose 1× on every day, although the venue contract invited leverage under high confidence. The trader repeatedly turned half-size recommendations into full-size labels, and the portfolio manager restored the intended size every time.

- *Performance.* The desk returned -0.53% while BTC fell -7.37%: capital was preserved, with a drawdown of 3.71%. Trend rules did better.

- *Skill.* None is detectable. Directional accuracy was 14/30. The result decomposes into a correct average stance (+1.65%) and losing timing (-1.98%).

- *Leakage.* The data controls hold. The models do not track October prices; the larger model recalls earlier prices almost exactly, which confirms the probe can detect memorization.

2 Experimental setup

Pre-registration. The protocol was written before any decision was run (`docs/hyperliquid/PLAN.md`) and amended once before the first decision. The amendment, at the user's request ("do not hesitate to use high leverage if you're sure"), lets the PM choose a leverage multiple $L \in [1, 5]$. The cap comes from the Kelly and liquidation analysis of the companion paper.

The policy variants, cost sensitivities and baselines were fixed before the first decision. MACD was added to the plan's baseline list at implementation time, also before any decision. Four analyses were added after results had been seen; none changes a reported performance figure:

- the fixed-leverage sensitivity (Table 4), added during the run in answer to a question about higher leverage;

- the exposure-versus-timing attribution;

- the desk-agreement statistics;

- the forced-estimate memorization probe, added because the first probe, which allowed the answer UNKNOWN, was uninformative.

Window. 30 daily decisions are dated 2026-09-30 to 2026-10-29. Each decision D uses information known by $(D + 1)$ 00:00 UTC, executes at 00:15 UTC on the next 15-minute bar's open, and holds 24 hours. The P&L window is therefore 2026-10-01 00:15 to 2026-10-31 00:15 UTC, all of October, with every period fully settled before this paper was written.

Agents. We run TradingAgents v0.7.1 with the Hyperliquid extension:

- four analysts: market, sentiment (archived sources), news (point-in-time), and derivatives;

- one bull–bear debate round and one risk-debate round;

- a cold-start memory.

The quick tier (analysts, researchers, trader, risk debaters, reflections) is `gpt-6-luna` and the deep tier (research manager, PM) is `gpt-6-sol`. Both are served through the user's ChatGPT plan with the provider's default sampling. Their reported training cutoffs are 18 May and 20 April 2026.

Account and costs. The account starts with $100,000 USDC on cross margin. Trading pays the tier-0 taker fee (4.5 bp) plus 1 bp of slippage per side, and hourly funding as printed by the venue, charged at the bar open as the oracle proxy. Liquidation occurs at a maintenance margin of 1.25% of notional. The rebalance band is 5% of equity.

Policy. The primary policy is long/short (Buy $+L$, Overweight $+0.5L$, Hold keeps, Underweight $-0.5L$, Sell $-L$). The *same decision sequence* is replayed four more ways:

- at 1×, ignoring the PM's multiple;
- long/flat at 1×;
- volatility-targeted at 40% annualized, capped at 2×;
- honoring the trader's stop-loss.

These are counterfactual, because the agents saw the primary policy's book.

Baselines. Each baseline is decided at the same cutoffs from closed daily candles and priced by the same engine:

- buy-and-hold (1× long, never rebalanced);
- 30-day time-series momentum [4];
- SMA(20) trend, long/short;
- the sign of the MACD histogram;
- RSI(14) reversion (long below 35, short above 65, flat between);
- cash.

Leakage controls. All controls of the companion paper are active:

- point-in-time slicing by bar close, verified by the canary test;
- the known-at rule for news;
- archived sentiment sources only;
- execution after the cutoff;
- memory visible two decisions later;
- a memorization and clock probe of both models (§8).

Reproducibility. Every venue response and news query is cached in the run directory. Every decision, fill, funding payment and 15-minute equity mark is in a JSONL ledger, and every agent report is saved. Replaying the ledger through the engine reproduces the recorded equity to within 0.0e+00 USDC. One command rebuilds every number, table and figure in this paper from the run directory, offline.

3 The market in October 2026

Over the P&L window the perp fell from 83,487 to 77,334 (-7.37%). The month had two phases (Figure 1):

- *1–21 October*: a range between roughly 80,000 and 87,000, with a failed breakout early in the month and sharp intraday swings around the September CPI release on 14 October.
- *22–30 October*: a decline to below 77,000, with the steepest drop on the last two days.

Daily volatility was 1.58% (about 30% annualized). The headlines the agents could read were dominated by a hot inflation print and Federal Reserve officials discussing further rate increases. The Crypto Fear & Greed index fell from Greed (74 on 1 October) to Fear (30 at month end).

Funding on the venue stayed at its floor for 66% of the 720 hourly prints, averaging +8.72% annualized. It was negative 6% of the time, and the average premium was -3.22 bp. A 1× long therefore paid a known carry: +708 USDC on $100,000 over the month.

4 What the desk did

Ratings and leverage. The portfolio manager issued 22 Underweight, 7 Overweight and 1 Hold ratings, and no Buy or Sell. It stated a leverage multiple on all 30 days, and every one was 1× (0 days above 1×). This happened although the venue contract told it to "use leverage decisively" when highly confident. The primary policy and its 1× counterfactual therefore coincide.

Net exposure was +0.5 on 2–7 and 22–23 October and −0.5 otherwise (Figure 1), with a mean of -0.23. The position changed sides five times and was otherwise left in place: 5 trades and a turnover of 4.5 times equity over the month.

Inside the desk. The research manager's recommendation and the PM's final rating agreed in direction on 29 of 30 days, and the PM toned down the research manager 1 time. The trader, whose schema allows only Buy, Hold or Sell, turned every Overweight into Buy and every Underweight into Sell. Read literally, those labels mean full size. The PM's text repeatedly corrected this, e.g. "the trader's 'Buy' label would incorrectly double the intended exposure". The sentiment analyst rated the month Mixed on 24 of 30 days.

The pattern is that of a cautious discretionary desk. It takes half-size positions, re-decides daily, and reads mostly short-horizon technical evidence (the 10-day EMA, MACD, the perp premium), with headlines treated as unverified context.

5 Performance

Table 1 and Figure 2 report net performance.

- The desk returned -0.53%, with an annualized volatility of 15.3% and a maximum drawdown of 3.71%.
- Buy-and-hold returned -8.13%, with a drawdown of 12.60%.
- Thirty-day time-series momentum and the MACD rule were short through most of the second half and earned +9.16% and +8.12%.
- The SMA(20) rule flipped repeatedly and finished flat.

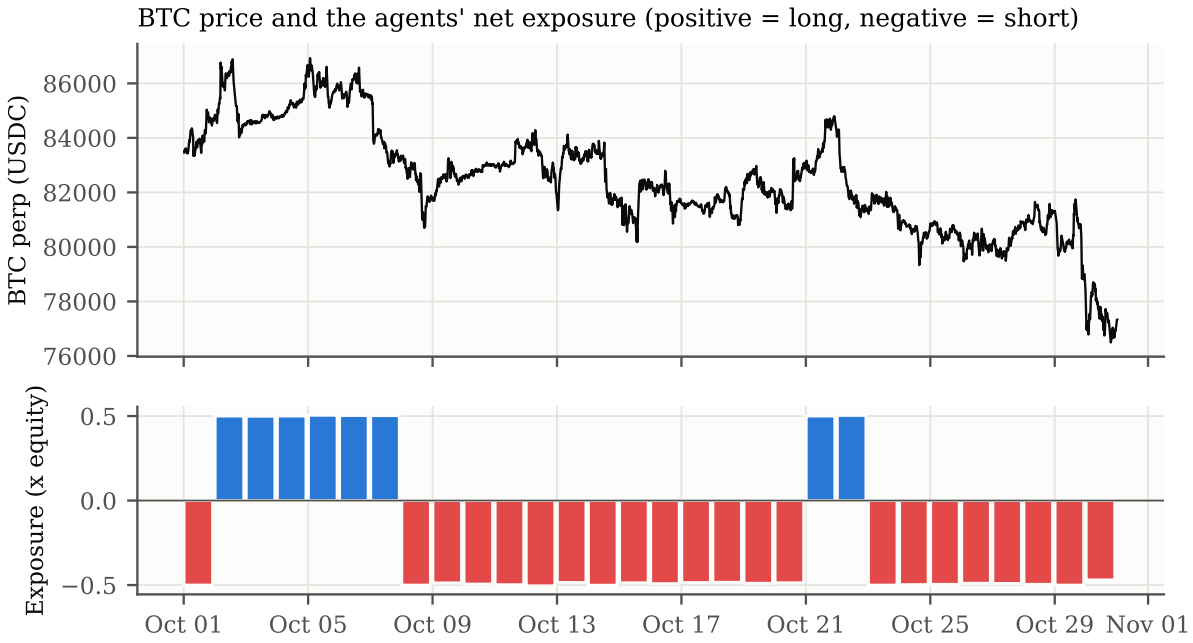

Figure 1: BTC perp price (15-minute closes) and the desk's net exposure after each daily execution. Blue is long, red short.

Where the P&L came from. Figure 3 splits the desk's P&L into price, fees, slippage and funding. Two points stand out:

- *Trading costs were small*: 199 USDC, including slippage, because the desk rarely traded.
- *Funding was a small gain*: the desk received 136 USDC net. The desk was mostly short while longs paid the floor rate.

6 Skill or exposure?

Beating buy-and-hold in a falling month is easy for anyone who is short. The question is whether the desk knew *when*.

Direction. The desk's sign was right on 14 of 30 days. The Pesaran–Timmermann statistic is -0.62 ($p = 0.731$), and the one-sided binomial p-value is 0.708. Table 2 and Figure 4 show what followed each rating:

- Overweight days were followed on average by a *fall* in BTC.
- Underweight days were followed by a small fall, but up and down days were equally likely.

The rank correlation between rating and next-day return is -0.13 (permutation $p = 0.497$).

Exposure versus timing. Following Lo [2], the gross P&L $\sum_t x_t R_t$ splits into two parts:

- a static part $T\bar{x}\bar{R}$, earned by the average exposure;
- an active part $\sum_t (x_t - \bar{x})(R_t - \bar{R})$, earned by varying the exposure over time.

The desk's average exposure of -0.23 earned +1.65%, its timing contributed -1.98%, costs -0.24% and funding +0.14%. The desk's lean was right for the month, and its timing gave that gain back.

Two features of the positions explain the timing loss:

Table 1: Net performance, 1–31 October 2026 ($100,000 start). Return is over the window; volatility, Sharpe and Sortino are annualized ($\sqrt{365}$); Max DD is measured on 15-minute marks. Turnover is total traded notional over equity. Fees include slippage; funding is in USDC (negative = received). The indented rows replay the agents' decisions under other policies; baselines decide at the same cutoffs.

Strategy	Return	Vol (ann.)	Sharpe	Sortino	Max DD	Turnover	Fees	Funding
TradingAgents-HL (primary, PM leverage ≤5x)	-0.53%	+15.3%	-0.35	-0.51	-3.71%	4.5	199	-136
same decisions, 1x	-0.53%	+15.3%	-0.35	-0.51	-3.71%	4.5	199	-136
same decisions, long/flat 1x	-2.93%	+9.3%	-3.86	-4.27	-4.11%	1.8	80	+149
same decisions, vol-target 40%	-0.09%	+19.7%	0.04	0.07	-4.64%	6.0	263	-191
primary + trader stop-losses	-0.76%	+15.2%	-0.54	-0.80	-3.94%	5.0	287	-135
Buy & hold (1x long)	-8.13%	+30.3%	-3.25	-3.77	-12.60%	1.0	45	+708
Time-series momentum (30 d)	+9.16%	+29.9%	3.71	6.48	-7.98%	3.2	143	+207
SMA(20) trend	-0.56%	+30.6%	-0.08	-0.11	-9.86%	7.1	313	-259
MACD histogram	+8.12%	+30.2%	3.29	6.59	-5.19%	1.3	57	-718
RSI(14) reversion	+0.53%	+2.1%	3.14	34.30	-1.26%	2.0	90	-30
Cash	+0.00%	+0.0%	–	–	+0.00%	0.0	0	+0

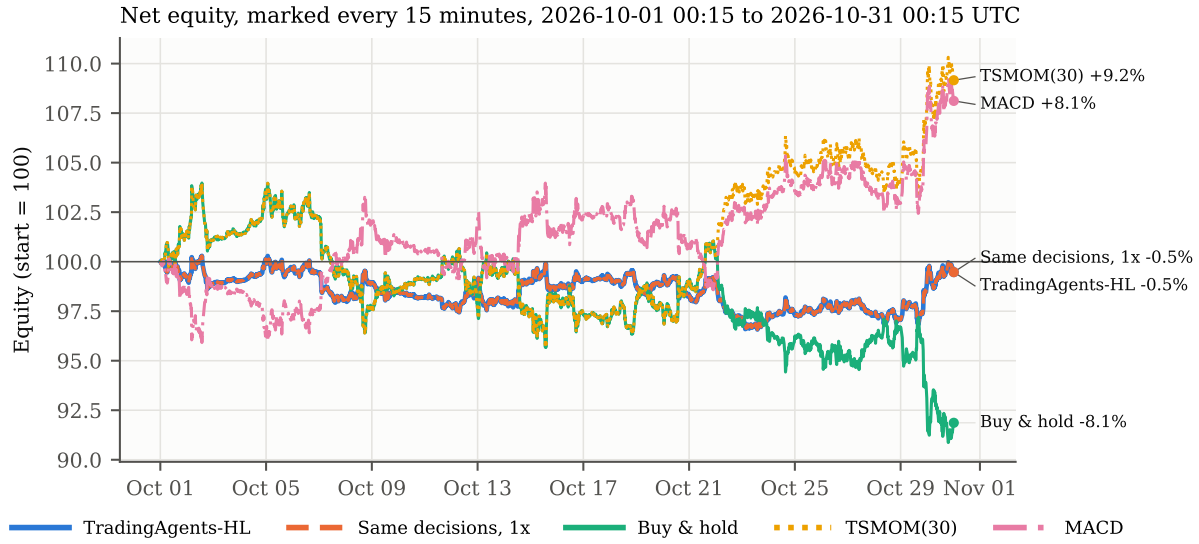

Figure 2: Net equity of the desk, its 1× replay (identical here, as no leverage was used), buy-and-hold, and the two best baselines, marked every 15 minutes.

- It turned long on 2 October and stayed long through the 6 October drop.
- It turned long again on 22 October, at a local high just before the decline.

Both times the long followed a rise. The short on 7 October followed a fall.

Random benchmarks. Two tests keep the desk's own propensities and destroy its timing:

- *Permutation*: shuffling its exposures across days beats it with probability 0.692 gross and 0.659 net.
- *Random-rating Monte Carlo*: drawing each day's decision from the desk's own rating mix (2,000 draws, full engine) returns +1.57% on average, with a 5–95% range of -5.16% to +7.40%. The desk sits at the 29th percentile (Figure 5).

A random ordering of the desk's own decisions would have done better more often than not.

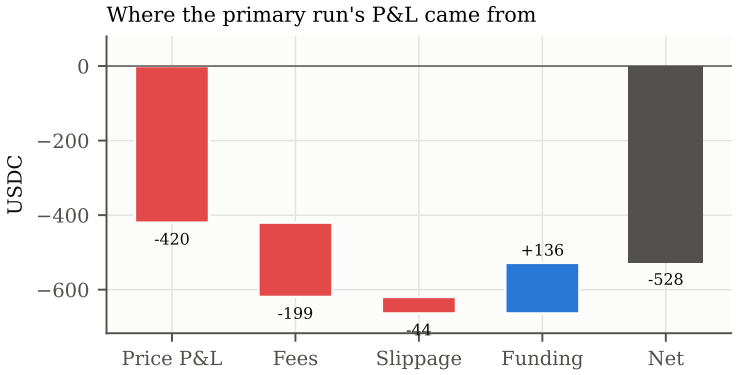

Figure 3: The desk's P&L, from the price move to the net result. Funding was received (positive bar) because the desk was short most of the month.

Table 2: What followed each PM rating: the BTC perp's return over that decision's holding period.

PM rating	Days	Mean next-period BTC return	Share up
Underweight	22	-0.15%	50%
Hold	1	+1.82%	100%
Overweight	7	-0.84%	29%

Sharpe inference. The desk's annualized Sharpe ratio was -0.35, with a stationary-bootstrap 95% interval of [-5.43, 4.41]. Its total return interval is [-6.18%, +5.67%]. The mean daily excess over buy-and-hold was +0.255% [-0.199%, +0.754%]; the interval contains zero, the large realized gap notwithstanding. The other measures:

- probabilistic Sharpe ratio against zero: 0.461;
- deflated Sharpe ratio across the five policy variants: 0.262;
- minimum track record length: ∞.

As the companion paper shows, with $T = 30$ any annualized Sharpe below about 6.8 is statistically indistinguishable from zero. This month cannot reject the hypothesis that the desk is a coin flip with a bearish tilt.

7 Robustness

Policies. On the same decisions (Table 1):

- *Long/flat* loses more: it keeps the losing longs and gives up the shorts.
- *Volatility targeting* is roughly flat.
- *Honoring the trader's stops* is slightly worse: stops closed positions on noise and paid fees twice.

Costs. Table 3 varies fees and slippage. Even frictionless trading leaves the desk negative, because the desk traded so little. Costs do not explain its result, and a fee tier or staking discount would not have changed it.

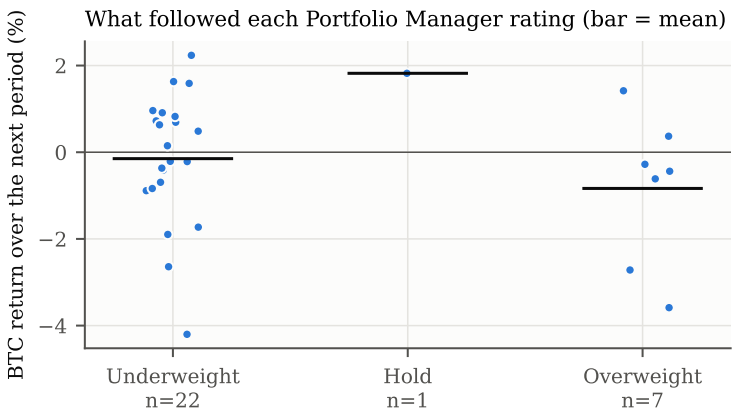

Figure 4: BTC return over the holding period following each rating (dots), with the mean (bar).

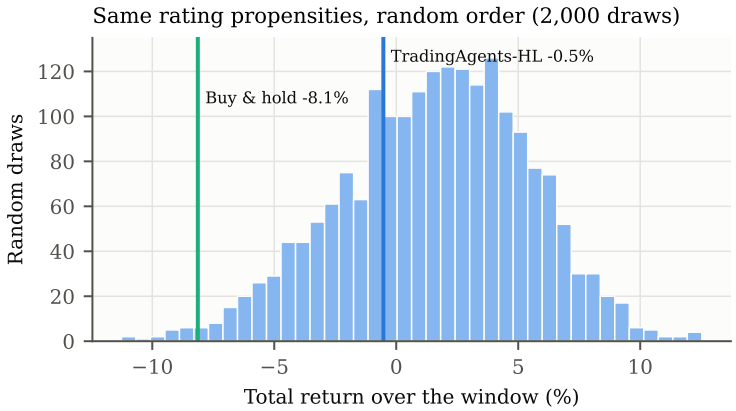

Figure 5: Net returns of 2,000 random decision sequences drawn from the desk's own rating mix, against the desk and buy-and-hold.

Leverage. Table 4 replays the same decisions with a fixed leverage multiple applied to every directional rating. This is a risk sensitivity, not a strategy: choosing the multiple after seeing the outcome would be look-ahead by the researcher.

- Leverage scales the loss and the fees without changing the sign.
- At 20× (positions of about 10× equity, because the ratings were half-size) the account loses about 40%, with a drawdown near two thirds.
- At the venue's 40×, the account is liquidated on 21 October.

The desk's refusal to use leverage was, in hindsight, its most valuable decision.

8 Leakage audit

Data path. Four checks cover the data the agents read.

- *Canary test.* It feeds every venue tool two synthetic histories that are identical before the cutoff and absurd after it, and passes: no tool output changes.
- *News lag.* The newest headline any decision could read was a median of 6 hours old at its cutoff (maximum 17). The other items were held back by the known-at rule, which affects the 78% of headlines stamped by date only.

Table 3: The primary run's decisions under alternative cost models.

Cost model	Return	Sharpe	Fees	Slippage
Base: tier 0 taker 4.5 bp + 1 bp slippage	-0.53%	-0.35	199	44
Taker, no slippage	-0.48%	-0.31	199	0
Slippage 2 bp	-0.57%	-0.38	199	89
Slippage 5 bp	-0.71%	-0.49	199	221
Fee tier 3 (3.0 bp taker)	-0.46%	-0.29	133	44
Tier 6 + Diamond staking (1.44 bp)	-0.39%	-0.24	64	44
All fills as maker (1.5 bp)	-0.35%	-0.20	66	0
Frictionless (no fee, no slippage)	-0.28%	-0.15	0	0

Table 4: The same decisions with a fixed leverage multiple on every directional rating, with liquidation enforced on 15-minute bars at the venue's maintenance margin.

Multiple L	Max position	Return	Sharpe	Max DD	Fees	Liquidated
1x	0.5x	-0.53%	-0.35	-3.71%	199	no
2x	1.0x	-1.09%	-0.29	-7.31%	397	no
5x	2.5x	-4.71%	-0.40	-18.49%	1,019	no
10x	5.0x	-13.80%	-0.44	-36.03%	2,022	no
20x	10.1x	-39.57%	-0.50	-64.91%	3,686	no
40x	20.7x	-95.52%	-3.11	-95.63%	5,113	2026-10-21

- *Memory.* Every lesson in the memory log was visible only from its resolution date, two decisions after the decision it concerns. The run log records each settlement before the decision that first reads it.
- *Replay.* Replaying the ledger reproduces the recorded equity exactly, so no input changed between the run and this analysis.

Clock. Asked for today's date with no date given, `gpt-6-sol` answered UNKNOWN and `gpt-6-luna` invented a date in 2025. Neither was told the real date by the provider.

Memorization. We asked each model for Bitcoin's daily close on every day of the window, and on the 15th of each month from August 2025 to April 2026, as controls. A first probe of ten dates allowed the answer UNKNOWN, and both models declined every date, including the controls. Forced to give a number, they produced the results in Table 5.

Table 5: Forced price estimates. Errors are medians of $|\hat{P}/P - 1|$ over 9 controls and 30 window days. "Guessed" and "realized" changes run from 1 to 30 October. "Corr." is the correlation between guessed and realized closes over the window, with a Fisher-z p-value.

Model	Control error	Window error	Guessed change	Realized change	Corr. (p)
`gpt-6-luna`	6.4%	22.8%	-5.0%	-8.8%	+0.31 (0.10)
`gpt-6-sol`	0.1%	10.0%	+11.8%	-8.8%	-0.24 (0.19)

The larger model has memorized prices: its control error is 0.1%. It recalls month-end closes from August 2025 to January 2026 almost exactly. From February 2026 its error jumps to 20–30%, so its effective knowledge of prices ends about three months before its reported cutoff.

On October 2026 its guesses are a flat \$75–95k with no relation to the realized path: a 10% median error and a correlation of -0.24. Its guesses rise 12% over the month while the price fell 9%.

The smaller model knows less even before its cutoff. In October it guesses between $75k and $125k with a 23% median error. Its weak positive correlation (+0.31, $p = 0.10$) is not significant, before any correction for testing two models.

A model that knew October would show the precision it shows on its controls. Neither does.

9 Sampling noise

Each decision is one sample from a stochastic system, so a different sample could have produced a different month. We re-ran every sixth decision (5 dates) on identical inputs:

- the same cutoff and cached data;
- the book the original run saw;
- the memory log as it stood then, with the decision itself removed.

Only the models' sampling differed.

Table 6: Original and re-run decisions on identical inputs.

Date	Original	Lev.	Re-run	Lev.
2026-10-05	Overweight	1.0	Overweight	1.0
2026-10-11	Underweight	1.0	Underweight	1.0
2026-10-17	Underweight	1.0	Underweight	1.0
2026-10-23	Underweight	1.0	Underweight	1.0
2026-10-29	Underweight	1.0	Underweight	1.0

All 5 re-runs reproduced the original rating and leverage (Table 6). The desk is therefore not a coin flip from one sample to the next.

Two caveats limit this:

- Four of the five dates fall in the long short regime, and the book the desk reads shows the position already held, which may anchor it.
- With five pairs, 5/5 agreement only establishes, at 95% confidence, that the desk gives the same rating at least 55% of the time ($0.05^{1/5} \approx 0.55$).

Within these limits, the month's result reflects the desk's policy more than its sampling noise. It also means the desk's poor timing would likely recur on a re-run.

10 Three decisions

6 October (Overweight, BTC −2.72%). With the book already at +0.5×, the PM kept it:

> "The modest-long case wins on direction: BTC-USD remains above its $84,831 10-day EMA, $83,845 Bollinger middle and rising $79,910 50-day average, with a +6.52% 30-day return and RSI of 63.48. But two softer closes, a negative MACD histogram, volume at 0.70× average and a modest −1.85 bp perp premium leave an $88,000 breakout unconfirmed; they cap conviction rather than establish a short thesis."

It also cited the $2,161 ATR as a reason not to lever. BTC fell 2.7% over the next 24 hours, the desk's worst day.

7 October (Underweight, BTC −1.73%). After that drop the desk flipped, with an explicit cost estimate:

> "From the current approximately +50% long, sell approximately 1× equity of BTC-USD notional (about 98,100 USDC at the quoted mark), including closing the long; estimated execution cost is about 54 USDC at 5.5 bp."

The flip followed the move rather than anticipating it. It was nevertheless right for the next day.

28 October (Underweight, BTC −4.20%). The desk kept its short, which needed no trade, through the month's largest drop. It listed what would make it wrong ("a sustained reclaim of the $81,556 VWMA and $81,919 50-day SMA") and why it was not shorting harder (one- and three-day gains, price above the 200-day average). This was its best day, at +2.1%.

These excerpts show the desk's strengths: numbers grounded in tools, explicit invalidation levels, awareness of costs and of the venue contract. They also show its weakness: its evidence is mostly the recent path of the price, and it reacts to moves rather than anticipating them.

11 Discussion and limitations

What this month shows. An LLM desk given an honest information set and honest costs behaved like a prudent discretionary trader. It sized small, refused leverage, explained itself, and preserved capital in a falling market. It showed no ability to time daily moves: its gross result is a correct average stance, a negative timing component, and statistics consistent with chance. Simple trend rules did better this month. One month, however, cannot rank strategies; a trending month is exactly when trend rules shine.

Limitations.

- *Sample.* Thirty observations give very low power (§6).
- *One path.* Each day is one sample of a stochastic system; Section 9 measures how often it changes its mind.
- *Counterfactual policies.* These replay decisions that were conditioned on the primary book.
- *Slippage* is modeled, not observed.
- *News* are headlines only, ranked by a search engine at fetch time, and lag by up to 17 hours.
- *FRED macro series* were not configured (no API key). The news analyst was told the data was unavailable, and macro events still reached it through headlines.
- *Prediction-market data* is live-only and was withheld.
- *Memory* started empty.
- *One model pair*: the results concern one pair of models through one provider.

Future work. The natural next steps are:

- a longer walk-forward window, which is the only way to gain power;
- repeated sampling of each day, to separate the desk's policy from its noise;
- hourly decisions with maker execution;
- an ablation of each analyst, to find which inputs, if any, carry information.

12 Conclusion

Over October 2026 the TradingAgents desk on Hyperliquid returned -0.53% while Bitcoin fell -7.37%. It kept its drawdown to 3.71% and never touched leverage. Its outperformance over buy-and-hold came from a bearish lean, not from timing. Every test of timing is consistent with chance, and the leverage the venue offers would have wiped it out. The value of the exercise lies less in the number than in the procedure: a month of LLM decisions, priced honestly and audited for leakage, whose result is reported with the uncertainty it carries.

A Daily ledger

Each row is one decision: the PM's rating and leverage, the resulting target exposure, the fill price, the BTC perp's return over the holding period, the account's net return, and the fees and funding paid in USDC. Negative funding means funding received.

Date	Rating	Lev.	Target x	Fill	BTC	Net	Fees	Funding
2026-09-30	Underweight	1.0	-0.50	83,487	+1.63%	-0.83%	22	-13
